Solution Architecture:

The Automated Network Request Management system is designed using a layered ServiceNow-based architecture to ensure automation, scalability, and security. The solution starts with the Service Portal where users submit network access requests through a structured catalog interface. These requests are validated at the intake layer using UI policies and client-side scripts to ensure correct and complete data entry.

Once submitted, the request enters the workflow orchestration layer, where Flow Designer evaluates conditions and routes the request for automatic approval or sends it to managers or security teams based on risk level. The business logic layer applies rules for access type, validation, and approval hierarchy to ensure proper decision-making.
